Apresentação

O presente trabalho representa um esforço de se obter, para o período 1991-2010, indicadores demográficos para as Grandes Regiões brasileiras com o objetivo de subsidiar não apenas estudos na área da demografia, bem como políticas sociais voltadas para estas regiões.

Deve-se esclarecer que os resultados apresentados têm caráter preliminar e, sobretudo, não constituem estimativas oficiais, pois são fruto de exercícios exploratórios que levaram em consideração as observações mais recentes investigadas pelo Censo Demográfico de 1991 (questionário CD 1.01 - Universo), pelas Pesquisas Nacionais por Amostra de Domicílios (PNADs) da década de 80 e pelo Registro Civil.

1. Projeção das populações das Grandes Regiões

As projeções das populações das Grandes Regiões por sexo e grupos etários quinquenais para o período 1991-2010 foram realizadas a partir das populações residentes estimadas para 1º de julho de 1991.

As estimativas dos saldos migratórios foram obtidas a partir das projeções vegetativas das populações das Grandes Regiões por sexo e grupos etários quinquenais e idades simples para 1º de julho de 1991, o que também demandou a estimativa de populações base para as Grandes Regiões em 1º de julho de 1980.

Considerou-se a razão de sexos ao nascimento como sendo igual a 1,04, segundo observado nas estatísticas vitais. Adotou-se, também, o suposto de que as populações regionais seriam fechadas às migrações internacionais.

A seguir é descrita a metodologia adotada nas projeções regionais com relação aos seguintes pontos:

- a. ajuste das populações base para 1º de julho de 1980 e 1991;
- b. estimativa da fecundidade das Grandes Regiões;
- c. estimativa da mortalidade das Grandes Regiões;
- d. conciliação das estimativas da fecundidade das Grandes Regiões com as do Brasil;
- e. conciliação das estimativas da mortalidade das Grandes Regiões com as do Brasil;
- f. estimativa da migração das Grandes Regiões;

1.1. Ajuste da população base das Grandes Regiões para 1º de julho de 1980 e 1991

As populações das Grandes Regiões¹ para 1º de julho de 1980 e 1991 foram calculadas a partir da utilização das distribuições relativas inter-regionais da população por sexo e grupos quinquenais de idade dadas, respectivamente, pelo Censo Demográfico de 1980 e de 1991. Estas distribuições foram aplicadas às populações do Brasil calculadas para 1º de julho de 1980 e 1991.

As populações do Brasil para 1º de julho de 1980 e de 1991 foram obtidas a partir da interpolação exponencial por sexo e grupos etários quinquenais entre as populações residentes dadas, respectivamente, pelos Censos Demográficos de 1970 e 1980, e de 1980 e 1991. Previamente a estas interpolações, as populações com idade ignorada foram distribuídas proporcionalmente por sexo e grupos etários quinquenais.

1.2. Estimativa da fecundidade das Grandes Regiões

As estimativas da fecundidade das Grandes Regiões seguiram o mesmo procedimento adotado na estimativa da fecundidade do Brasil².

As estimativas iniciais da Taxa de Fecundidade Total utilizadas no ajuste das funções logísticas referem-se ao período compreendido entre 1963 e 1990. Especificamente para as Regiões Sudeste e Sul, adotou-se nos ajustes logísticos Taxas de Fecundidade Total limites de 1,80, para as demais Grandes Regiões, este valor foi de 2,10.

¹ Nestas projeções, a Região Centro-Oeste continua a incorporar o Estado de Tocantins.

² Vide *Metodologia adotada na projeção preliminar da população do Brasil para o período 1980-2020*.

1.3. Estimativa da mortalidade das Grandes Regiões

Assim como as estimativas da fecundidade, as estimativas de mortalidade das Grandes Regiões foram realizadas a partir da aplicação do mesmo procedimento adotado para a estimativa da mortalidade do Brasil³.

Para as Regiões Sudeste, Sul e Centro-Oeste foram construídas tábuas de mortalidade para os anos de 1980 e 1990. Nestas Regiões, a tábua de mortalidade para 1985 foi obtida a partir de uma interpolação linear dos logaritmos das taxas específicas de mortalidade dos anos de 1980 e 1990. Este processo de interpolação foi executado pelo programa RUP (Rural-Urban Projections) utilizado nas projeções populacionais.

Já para as Regiões Norte e Nordeste, foram incorporadas tábuas de mortalidade correspondentes ao ano de 1985, um vez que nestas Regiões evidenciaram-se marcadas diferenças entre as estruturas de mortalidade de 1980 e 1985.

1.4 Conciliação das estimativas de fecundidade das Grandes Regiões com as do Brasil

A partir das estimativas iniciais de fecundidade e mortalidade das Grandes Regiões, foram realizadas projeções vegetativas das populações por sexo e grupos quinquenais de idade para o período 1980-1991.

Considerando-se o número de nascimentos por idade da mãe para o Brasil, obtido a partir da projeção realizada precedentemente, e para cada uma das Grandes Regiões para os anos de 1980, 1985 e 1990, procedeu-se à conciliação das taxas específicas de fecundidade das Grandes Regiões com as do Brasil, de modo que os totais de nascimentos por idade da mãe obtidos a partir da soma das

³ Vide *Metodologia adotada na projeção preliminar da população do Brasil para o período 1980-2020*.

projeções vegetativas das Grandes Regiões fossem iguais aos totais de nascimentos por idade da mãe derivados da projeção nacional para cada um destes anos.

Tomando-se, então, $B_r(x, x+n)$ como o total de nascimentos à mães pertencentes ao grupo etário com x a $x+n$ anos completos na Grande Região r , $P_r(f, x, x+n)$ como a população de mulheres pertencentes ao grupo etário com x a $x+n$ anos completos na Grande Região r , e $f_r(x, x+n)$ como a taxa específica de fecundidade de mulheres pertencentes ao grupo etário com x a $x+n$ anos completos na Grande Região r , tem-se que:

$$B_r(x, x+n) = P_r(f, x, x+n) \times f_r(x, x+n) \quad (1)$$

Do mesmo modo, para o total do país:

$$B(x, x+n) = P(f, x, x+n) \times f(x, x+n) \quad (2)$$

Somam-se os nascimentos por idade da mãe calculados a partir da equação (1):

$$BR(x, x+n) = \sum_{r=1}^5 B_r(x, x+n) \quad (3)$$

A conciliação das taxas específicas de fecundidade das Grandes Regiões consistiu em se

calcular o fator $R_f(x, x+n)$ e, a partir deste, determinar $f_r^*(x, x+n)$ que é a taxa específica de fecundidade conciliada de mulheres pertencentes ao grupo etário com x a $x+n$ anos completos na Grande Região r :

$$R_f(x, x+n) = \frac{B(x, x+n)}{BR(x, x+n)} \quad (4)$$

$$f_r^*(x, x+n) = R_f(x, x+n) \times f_r(x, x+n) \quad (5)$$

Para os anos entre 1980, 1985 e 1990, o total de nascimentos estimados para o Brasil e para cada uma das Grandes Regiões foram conciliados a partir do ajuste das Taxas de Fecundidade Totais das Grandes Regiões com as do Brasil.

1.5 Conciliação das estimativas de mortalidade das Grandes Regiões com as do Brasil

A conciliação das taxas específicas de mortalidade das Grandes Regiões com as do Brasil foi realizada a partir de procedimento análogo ao adotado para a conciliação das taxas específicas de fecundidade, ou seja, calcularam-se taxas específicas de mortalidade conciliadas de modo que os totais de óbitos por idade e sexo obtidos a partir da soma das projeções vegetativas das Grandes Regiões igualassem os totais de óbitos por idade e sexo derivados da projeção nacional para os anos de 1980, 1985 e 1990.

Considerando-se, então, $D_r(x, x+n)$ como o total de óbitos de pessoas pertencentes ao grupo etário com x a $x+n$ anos completos na Grande Região r , $P_r(x, x+n)$ como a população pertencente ao grupo etário com x a $x+n$ anos completos na Grande Região r , e $m_r(x, x+n)$ como a taxa específica de mortalidade dos indivíduos pertencentes ao grupo etário com x a $x+n$ anos completos na Grande Região r , tem-se que:

$$D_r(x, x+n) = P_r(x, x+n) \times m_r(x, x+n) \quad (6)$$

Do mesmo modo, para o total do país:

$$D(x, x+n) = P(x, x+n) \times m(x, x+n) \quad (7)$$

Somam-se os óbitos por idade calculados a partir da equação (6):

$$DR(x, x+n) = \sum_{r=1}^5 D_r(x, x+n) \quad (8)$$

A conciliação das taxas específicas de mortalidade das Grandes Regiões consistiu em se obter

o fator $R_m(x, x+n)$ e, a partir deste, determinar $m_r^*(x, x+n)$ que é a taxa específica de mortalidade conciliada de indivíduos pertencentes ao grupo etário com x a $x+n$ anos completos na Grande Região r :

$$R_m(x, x+n) = \frac{D(x, x+n)}{DR(x, x+n)} \quad (9)$$

$$m_r^*(x, x+n) = R_m(x, x+n) \times m_r(x, x+n) \quad (10)$$

O procedimento de conciliação descrito acima, foi realizado separadamente para homens e mulheres, ou seja obtiveram-se fatores $R_m(x, x+n)$ para cada um dos sexos.

1.6 Estimativa da migração das Grandes Regiões

Com base nas taxas específicas de fecundidade e mortalidade conciliadas para as Grandes Regiões, realizaram-se novas projeções vegetativas das populações por sexo e grupos quinquenais de idade para 1991.

Para os indivíduos com idade superior a 10 anos de idade completos em 1º de julho de 1991, a diferença entre a população estimada e a projetada vegetativamente para 1º de julho de 1991 equivale ao saldo migratório por sexo e grupos etários quinquenais no período 1980-1991.

Já para os indivíduos entre 0 e 10 anos de idade completos em 1º de julho de 1991, a diferença entre a população estimada e a projetada vegetativamente para 1º de julho de 1991 incorpora o que é conhecido como efeito direto e efeito indireto da migração.

O efeito direto da migração é o próprio saldo migratório, ou seja, filhos que migraram com as suas mães após terem nascido na região de origem. No efeito indireto da migração englobamos aqueles indivíduos que nasceram na região de destino após suas mães terem migrado, ou seja, deixaram de nascer na região de origem em função da migração de suas mães.

Supondo que tanto a migração de mães quanto o nascimento dos filhos destas ao longo do período 1980-1991 ocorreu de forma linear, podemos calcular o efeito direto e indireto para os indivíduos pertencentes aos grupos etários de 0 a 4 e 5 a 9 anos e com 10 anos de idade completos em 1991. O efeito indireto será, respectivamente, igual a 77,3%, 31,8% e 4,6% da diferença entre a população estimada e a projetada vegetativamente.

Com base nos saldos migratórios por sexo e grupos quinquenais de idade das Grandes Regiões no período 1980-1991, considerou-se que a idade média dos migrantes no momento da migração era 5 anos mais jovem que a idade destes em 1991.

Assim, os migrantes com, por exemplo, 40 a 44 anos de idade completos em 1º de julho de 1991 possuíam, no momento de sua migração, em média 35 a 39 anos de idade completos.

Analogamente, os migrantes com 80 e mais anos de idade completos em 1º de julho de 1991 possuíam, também no momento de sua migração, em média 75 e mais anos de idade completos. Neste sentido, mantiveram-se as distribuições relativas do saldo migratório dos grupos de 75 a 79 e 80 e mais anos de idade completos com relação ao saldo do grupo de 75 e mais anos de idade completos.

Enfim, a partir das estruturas de saldos migratórios onde a idade média dos migrantes no momento da migração era 5 anos mais jovem que a idade destes em 1991, estimou-se proporcionalmente o saldo migratório anual de cada Grande Região por sexo e grupos quinquenais de idade.

1.7 Projeção das populações das Grandes Regiões para o período 1991-2010

A partir das populações estimadas para 1º de julho de 1991, e das estimativas da fecundidade, mortalidade e migração, projetaram-se, através do método dos componentes, as populações das Grandes Regiões por sexo e grupos etários quinquenais para 1º de julho de 2010.
